Recombination In Semiconductors

In the solid-state physics of semiconductors, carrier generation and carrier recombination are processes by which mobile charge carriers (electrons and electron holes) are created and eliminated. Carrier generation and

recombination processes are fundamental to the operation of many optoelectronic semiconductor devices , such as photodiodes , light-emitting diodes and laser diodes .

flow from the emitter to the collector, and a few of them enter the base to recombine with the holes and form the recombination current. If an electron combines with a hole, it gets nullified. How then, does it form the recombination current?

Recombination is the reverse process where electrons and holes from the conduction respectively valence band recombine and are annihilated. In semiconductors several different processes exist which lead to generation or recombination, the

2.3 Carrier Generation and Recombination

Semiconductors are characterized by two types of mobile carriers, electrons in the conduction band and holes in the valence band. Both bands are separated by an energy gap. When an electron

loses energy and falls into the valance band, it gets neutralized by a hole which absorbs its energy. This process is called recombination and the energy of recombination will emerge as a photon.

on the behavior of semiconductor devices. This is because surfaces and interfaces typically contain a large number of recombination centers because of the abrupt termination of the semiconductor crystal, which leaves a large number of electrically active states.

recombination mechanisms in semiconductors Band-to-band recombination occurs when an electron falls from its state in the conduction band into the empty state in the valence band which is associated with the hole. This band-to-band transition is typically also a radiative transition in direct bandgap semiconductors.

recombination can be written as $R_{\text{Auger}} = C_{\text{Auger}} n^3$, where $C_{\text{Auger}} = C_{\text{eehh}} + C_{\text{hhcc}}$. Auger recombination is a well-known effect in smaller bandgap semiconductors, but the effect of Auger recombination decreases strongly with increasing bandgap (Hader et al., 2008).
