Threedimensional Analysis Of Spinal Deformities

To compare 3D postoperative deformity correction using two distinct commonly utilized techniques for the treatment of adolescent idiopathic scoliosis (AIS). AIS patients with major thoracic (Lenke 1-2) curves at two sites who underwent deformity correction via posterior spinal instrumented fusion using one of two distinct techniques were retrospectively reviewed.

Purpose: Understanding how to classify and quantify three-dimensional (3D) spinal deformities remains an open question in adolescent idiopathic scoliosis. The objective of this study was to perform a 3D manifold characterization of scoliotic spines demonstrating thoracic deformations using a novel geometric and intuitive statistical tool to determine patterns in pathological cases.

In this study, we used 3-dimensional (3D) computed tomography (CT)-based imaging analysis to calculate the change in spinal canal length resulting from spinal deformity correction.

Introduction Scoliosis is a multifactorial three-dimensional (3D) spinal deformity that always involves elemental deformities in the three main planes: lateral curvature in frontal, anteroposterior (mainly lordotic) deviation in sagittal, and (very characteristically) vertebral axial rotation in the horizontal plane.

The Pearson χ^2 test and Spearman analysis were used to determine the incidence of rib anomalies and spinal deformities, as well as the interaction between microtia and thoracic deformities. The differences with a P -value <0.05 were considered as statistically significant.

Abstract Current two-dimensional methods for quantifying scoliosis are inadequate. A radiographic method has been developed which determines the three-dimensional location and rotation of each vertebra. Posteroanterior and posterior oblique radiographs of the spine are obtained with the patient standing within a reference frame.

The standard clinical radiographs do not demonstrate the 3-D spinal shape, but a new self-calibration method recently proposed by Kadoury et al. , enables 3-D reconstruction from uncalibrated frontal and lateral X-rays, making it now possible to perform retrospective 3-D analysis. The basis of this new self-calibration employs identified anatomical landmarks on the patient's spine, in order to calibrate and subsequently reconstruct the spine in 3-D without the need of a calibration apparatus.

It has been argued that use of these terms is misleading, since spinal deformity leads to a truly 3-D shape of the vertebral body line, and even a part of it cannot be adequately represented by a 2-D plane.

Three-dimensional findings in congenital-deformed vertebrae included several types of laminae and clearer definitions of each type of anomalous vertebrae.

RESULTS: With the 3-D chest CT images, a total of 68 cases (28.5%) were documented with thoracic deformities including 60 cases (25.1%) with rib anomalies, 20 cases (8.4%) with spinal deformities, and 12 cases (5.0%) with ...
